Homework Assignment 1

Rukmal Weerawarana

FE 621: Computational Methods in Finance

Instructor: Ionut Florescu

2/20/2019

rweerawa@stevens.edu | 104-307-27 Department of Financial Engineering Stevens Institute of Technology

Overview

In this Homework Assignment, we explore various numerical optimization methods through the lens of the Black-Scholes-Merton Option pricing model (Shreve2004). Using this, we calculate explore the implied volatility of options for various assets traded on the market. Furthermore, we also explore numeric methods of differential calculation to compute the Greeks of these candidate options. Finally, we explore numeric integration and the behavior of various quadrature methods.

Unless otherwise stated, the following shorthand notation is used to distinguish between dates:

- **DATA1** Wednesday, February 6 2019 (2/6/19)
- **DATA2** Thursday, February 7 2019 (2/7/19)

The content of this Homework Assignment is divided into three sections; the first discusses data gathering, formatting, and a discussion of the assets being examined. The second contains data analysis, and an exploration of implied volatility through the Black-Scholes-Merton pricing framework and related computations. Finally, the third section discusses numerical integration and the convergence of various quadrature rules.

See Appendix?? for specific question implementations, and (Weerawarana2019) for full source code of the fe621 Python package.

1 Data Overview

1.1 Asset Descriptions

1.1.1 SPY - SPDR S&P 500 ETF (StateStreetGlobalAdvisors2019)

The S&P 500 (i.e. Standard & Poor's 500) is a stock market index tracking the 500 largest companies on the American Stock Exchange by Market Capitalization. In this case, the market capitalization is defined as the number of outstanding shares, multiplied by the current share price. A stock market index is designed to be a metric that can be used by market observers as a benchmark to gauge the relative health of the stock market, by analyzing the aggregate performance of its largest components.

However, this index is not the same as the SPY ETF. An ETF (Exchange Traded Fund) is a basket of stocks that is designed to track a specific index or benchmark. That is, it provides investors with exposure to a index or benchmark, without having to own all of the underlying assets that constitute a composite asset. In addition to more liquidity, this type of investment also provides lower transaction costs and required minimum investment to gain exposure to a given index or benchmark. It is traded on an exchange, akin to a typical traded asset.

1.1.2 VIX - CBOE Volatility Index (CBOEChicagoBoardOptionsExchange2019)

The CBOE (*Chicago Board Options Exchange*) volatility index, *VIX* is an exchange traded product (*ETP*) designed to give investors exposure to the market's expectation of 30-day volatility. It is priced using a large set of implied volatility of put and call options on the S&P 500 index to gauge investor sentiment. Typically, the price of the VIX has an inverse relationship to the price of the S&P 500 index. Similar to an ETF, an ETP is also traded on an exchange as a typical traded asset.

1.2 Data Gathering

For the assignment, we downloaded monthly options on $Amazon\ Inc.$ (ticker: AMZN) and $S&P\ 500\ ETF$ (ticker: SPY) at various strike prices for the following dates:

- 02/15/19 Friday, February 15 2019;
- 03/15/19 Friday, March 15 2019;
- 04/18/19 Thursday, April 18 2019.

A wide variety of option strike prices were considered, with the following ranges:

- *AMZN* \$1555 to \$1725 in increments of \$5 (35 strike prices);
- SPY \$256 to \$284 in increments of \$1 (29 strike prices).

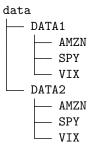

Intra-day minute closing price data was gathered for both put and call options with expiration dates and strike prices detailed above. This intra-day data was gathered for the trading day 2/6/19 (February 6 2019; **DATA1**). Additionally, intra-day minute closing price data was also downloaded for each of the underlying assets. This data was downloaded for both 2/6/19 (February 6 2019; **DATA1**), and 2/7/19 (February 7 2019; **DATA2**).

This data detailed above was gathered utilizing *Rblpapi* (**Armstrong2018**), which provides an R interface to data on the Bloomberg Terminal (**BloombergL.P.2019**). The data download was automated, and corresponding intra-day prices for each of the options were output to individual files. The source code for this implementation is available in Appendix ??.

Furthermore, as a proxy for the *risk-free rate*, we chose to utilize the effective Federal Funds Rate (FFR). This is the interest rate at which depository institutions in the United States lend reserve balances to other depository institutions overnight. This data was gathered for both dates, and correspond to **DATA1** and **DATA2**. The effective FFR is published daily by the US Federal Reserve Board of Governors, and are expressed as yields per annum (**BoardofGovernorsoftheFederalReserveSystem2019**).

1.2.1 Data Cleaning

For easier programmatic access, the data was placed in a hierarchical structure, corresponding to the **DATA1**, **DATA2** data division. Each of the option and asset prices for the corresponding days were placed in the requisite sub-folders. This directory structure is reproduced below.

8 directories

Option price filenames were changed to OOC format option names, discussed further below. This was done utilizing a cleaning script, written in Python. This script employs utility functions from the fe621 Python package (Weerawarana2019). The cleaning script is reproduced in Appendix ??.

1.3 Option Naming Convention

A modern convention for naming option contracts was proposed by the Options Clearing Commission (OCC) in 2008 (**OptionsSymbologyInitiative2008**), and adopted in 2010. The OCC is an organization that acts as both the issuer and guarantor for option and future contracts. The OCC is governed by the Securities and Exchange Commission (SEC) and the Commodities Futures Trading Commission (CFTC). The current convention for option naming is best explained by example.

Consider the option code, AMZN190215C019600000. This corresponds to a **Call Option** on **Amazon Inc.** (**AMZN**), with a strike price of \$1960.00 and an expiration date of 2/15/19 (February 15 2019). The methodology of this nomenclature is explained in detail below:

AMZN190215C01960000

- AMZN Ticker of the company (arbitrary length; always first sequence of characters)
- 19 Expiration year of the contract (shortened to two digits, i.e. $2019 \rightarrow 19$)
- 02 Expiration month of the contract
- 15 Expiration day of the contract
- C Type of option (C for call, P for put)
- 01960 Dollar component of strike price (in \$; always 5 digits)

Similarly, the following option code corresponds to a Put Option on SPDR S&P 500 ETF (SPY), with a strike price of \$287.50 and an expiration date of 3/15/19 (March 15 2019):

SPY190315P00287500

Finally, the following option code corresponds to a Call Option on CBOE Volatility Index (VIX), with a strike price of \$16.35 and an expiration date of 4/18/19 (February 18 2019):

VIX190418C00016350

A Appendix

A.1 Question 1 Implementation

A.1.1 Bloomberg Data Download

```
library("Rblpapi")
  # Connect to Bloomberg Terminal backend service
  blpConnect(host = "localhost", port = 8194)
7
  #-----
8
   # Data Download Functionality
9
10
11
  getPrice <- function(security, startTime, endTime, timeZone) {</pre>
12
13
    # Downloads and returns the closing price of a given security
    # for each minute in the trading day.
14
15
16
    # Args:
17
        security: Name of the security to be downloaded.
18
         startTime: Datetime object with the start time.
        endTime: Datetime object with the end time.
19
20
        timeZone: Time zone of the target start and end times.
21
22
    # Returns:
23
        DataFrame with the closing price for each minute in the
24
        trading day.
25
26
     # Getting price data
27
     data <- getBars(security = security, barInterval = 1,</pre>
28
                     startTime = startTime, endTime = endTime,
29
                     tz = timeZone)
30
     # Isolate time and closing price
31
     data <- data[c("times", "close")]</pre>
32
33
34
